

Synthesis of Some Derivatives of the Alkdiin Carboxylic Acids on the Basis of Diacetylene SCV/79-29-6-40/72

halides. By this method the condensation of 1,3-chloro-bromo propane with n.-butyl diacetylene and diacetylene was carried out which hitherto had not been described in publications. In the latter case a monosubstituted derivative was formed. The diacetylene hydrocarbons obtained are mobile liquids with a characteristic smell, unstable already at room temperature, sensitive to light and more stable in the form of their ether solutions in the cold and in the dark. The n.-butyl- and 1-chloro propyl diacetylenes were accordingly converted into the octa-5,7-diin-8- and chloro-hepta-4,6-diin-7-carboxylic acid. In the case of longer standing in methanol in the presence of sulphuric acid the methyl esters of these acids were obtained, which were used for the amide synthesis without being purified. The derivatives of the alkdiin carboxylic acid obtained were biologically investigated. Among them the isopropyl amide and the copper salt of the octa-5,7-diin-8-carboxylic acid show a bacteriostatic effect with respect to the acid stable bacteria. Copper salt is efficient even against diphtheria bacilli. There are 7 references, 2 of which are Soviet.

TITLE: Structure of Monomeric Arseno Compounds

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol 131, Nr 5, pp 1074-1076 (USSR)

TEXT: It was proved by the authors in their paper that among all determinations of the molecular weight of arsenobenzene given in literature, only the methods by F. F. Blicke and F. Smith (Ref 10) are correct. All results obtained with other methods are distorted by resinification reactions. All arseno compounds hitherto described can be divided into two groups: I) colored, amorphous, non-crystallizing and non-distillable compounds. Some of these are insoluble in any solvent, others are soluble in appropriate solvents only, when they form viscous solutions. They were found to be polymers (see scheme). II) Colorless and easily crystallizing, distillable substances. They have the character of monomers. A cyclic structure was demonstrated for arsenomethane (III). The situation is more complicated with arsenobenzene: its molecular weight is rather different according to the individual researchers and techniques used (399.8, 402, 642 and, finally, according to F. F. Blicke and F. Smith 895 and 915). It was obviously because of this multiplicity that the structural formula  $R-As=As-R$  ( $R = C_6H_5$ ) was adopted. It is, however, improbable that a compound with such a

Card 1/3

S/020/60/131/05/025/069  
B011/B117

structure should be colorless. The authors presume that the difference between above-mentioned results could be explained with reference to the instability of the arsenobenzene. Its resinification (polymerization) products are most readily oxidized in air up to  $C_6H_5AsO$ . The latter as well as the resinification products of arsenobenzene are very readily soluble in many solvents, but are difficult to detect whereby unreliable results for the molecular weight of arsenobenzene are obtained. The authors arrived at the conclusion that reliable data on the structure of arsenobenzene can be obtained only when the X-ray structural analysis method is used. The thin, almost colorless (yellowish) crystals of arsenobenzene form thin needles. Axis b is the longer one. The simpler shapes are pinacoids  $\{100\}$  and  $\{001\}$ . From data obtained, the authors came to the conclusion that there are 3 crystallographically non-equivalent As atoms contained in a cell. As is proved by the established projection of the electron density (Fig 1), the arsenobenzene molecule is a cyclic system consisting of As atoms. One phenyl group is bound to each As atom. The cycle is six-membered (IV). Such cyclic molecules occupy the position of centers of symmetry within the crystal. The cycle is not arranged in one plane, but has a chair-shaped configuration and a valence angle As - As - As of  $93^\circ$ . The outer valence angles As - As - C are

Card 2/3

6999b

Structure of Monomeric Arseno Compounds

S/020/60/131/05/025/069  
B011/B117

$99 \pm 3^\circ$ . The lengths of the bonds As - As are 2.44 Å, and that of the bonds C - As = 1.96 Å. Provided that data for arsenobenzene given by Blicke and Smith are correct, then their data on the molecular weights of p-arsenotoluene and p-arsenoanisole are also reliable. Hence, the authors come to the conclusion that there are no arseno compounds with a structure  $R - As=As - R$  at all. They actually are either polymers (I) and (II) or cyclic compounds (III) and (IV). There are 1 figure and 10 references, 3 of which are Soviet.

TITLE: Cyclic oxocompounds as potential antiviral agents

SOURCE: Farmakologiya i toksikologiya, v. 29, no. 5, 1966, 597-600

TOPIC TAGS: cyclic oxocompound, antiviral agent, drug effect, pharmacology, virus, virology, nucleic acid, protein

ABSTRACT: The antiviral properties of the compounds in Table 1 were determined. These compounds were tested on influenza RR-8 type A virus *in vitro* and *in ovo* in tissue cultures. All possessed antiviral activity *in vitro* and some inhibited viral growth in chick embryo epithelium. These cyclic oxocompounds are highly reactive and are thought to produce their inhibitory activity by acting on viral protein in such a way that the viruses cannot adhere to the cell membranes of sensitive cells. Related compounds have been effective against keratitis infections when applied locally. Quinone derivatives with comparatively low redox po-

tentials have been discovered to possess good antiviral properties, thus refuting a theory that antiviral activity and high Eh were connected. The compounds involved in the present study were tested more for their effects on amino groups of nucleic acids and proteins with emphasis on their extracellular interference with the virus and only secondarily for their intracellular effects on reproducing viruses. The object was to find a compound that reacts easily with viral protein but which is comparatively indifferent to the protein of the host cell. The configuration of the molecule of the compound is very important and plays a great role in the specificity of the drug. Little antiviral activity was displayed by 4-hydroxy-beta-napthoquinone and its tautomeric form 2-hydroxy-alpha-napthoquinone. The most effective compound was 7-hydroxy-beta-napthoquinone. The activities of the other compounds tested are shown in Table 1. The most effective virus neutralizing compounds (no. I, II, III, VIII, XI, and XV) were used in the treatment of pneumonia in white mice, but were not effective. Orig. art. has: 1 table.

AUTHORS: Dzhelepov, B.S., Kraft, O.Ye., Zhinkina, V.B.

TITLE: Positrons in the Radiation of the Radioactive Isotope In<sup>114</sup>  
(Pozitrony v izluchenii radioaktivnogo izotopa In<sup>114</sup>)

PERIODICAL: Izvestiya Akad. Nauk SSSR, Ser. Fiz., 1957, Vol. 21, Nr 7,  
pp. 978 - 984 (USSR)

ABSTRACT: The radioactive isotope In<sup>114</sup> possesses the possibility of a concurrent  $\beta^+ - \beta^-$ -decay. It lies between two stable isobars whose charge differs by two units: Cd<sup>114</sup> and Sn<sup>114</sup>. This decay is fully described and reference is made to work<sup>48</sup> done in this field by other authors. The radioactive isotope In<sup>114</sup> possesses two isomers with half-decay periods of 50 days and 72 seconds. The 50 days isomer is converted to its ground state In<sup>114</sup> by emitting either a  $\gamma$ -quantum with the energy of 192 keV or a conversion electron. The authors further give a survey of data on the In<sup>114</sup> decay and report on the work done by other authors in this field, where it was for the first time reported on positrons. In order to estimate the intensity and the limiting energy of the positrons the authors used as source an indium foil covered by aluminum as reabsorber. The  $\beta$ -spectrum of

Card 1/2

Positrons in the Radiation of the Radioactive Isotope  $\text{In}^{114}$  48-7-10/21

$\text{In}^{114}$  was investigated by the authors by means of a magnetic  $\beta^-$ -spectrometer. On figure 1 the test spectrum of the positrons of  $\text{In}^{114}$  is represented. For measuring the background a slide for screening off the  $\beta$ -particles was inserted. Figure 2 shows the positron spectrum as result. In order to exclude errors the  $\beta$ -spectrum of  $\text{In}^{114}$  was measured (under the same conditions as the positron spectrum), and the resulting  $\beta$ -spectrum is represented on figure 3. Figure 4 records the Fermi diagram for the  $\beta^-$ -spectrum of  $\text{In}^{114}$ . The dependence of the corrections on the energy is represented on figure 5. In order to estimate how far the corrections were correct, they were plotted on the ordinates of a conversion line (figure 6). Figure 7 shows the Fermi diagram for the positron spectrum of  $\text{In}^{114}$ . Figure 8 records the scheme of the  $\text{In}^{114}$  decay. There are 8 figures and 23 references, 5 of which are Slavic.

TITLE: A Study of the  $\beta^+$  - Decay of  $\text{Ho}^{160}$  (Issledovaniye  $\beta^+$  - raspada v  $\text{Ho}^{160}$ ).

PERIODICAL: Doklady AN SSSR, 1957, Vol. 116, Nr 4, pp. 581-583 (USSR).

ABSTRACT: The authors investigated the holmium-fraction, which was separated from a target irradiated by protons with an energy of 660 MeV. The active substance was deposited in a thin layer on a cellophane with a thickness of  $17\mu$ . The authors ascertained from a measurement of the electron spectrum of holmium the lines corresponding to the transitions  $197 \pm 5$ ;  $287 \pm 10$ ;  $545 \pm 20$ ;  $652 \pm 20$ ;  $730 \pm 20$ ;  $874 \pm 25$ ;  $974 \pm 25$  and  $1315 \pm 30$  keV. The half life of these lines amounts to 4.5 to 6 hours. The conversion electrons corresponding to the transitions 196; 298; 539; 648; 730; 1876; 967 keV appertain to the isotope  $\text{Ho}^{160}$ , which has a half life of 5.3 hours. For these reasons, the conversion spectrum of the sample is probably due entirely to  $\text{Ho}^{160}$ . According to the measurements of the authors this spectrum consists of a composite curve. The Curie diagram of this spectrum is also given here. This diagram shows clearly four components of the  $\beta^+$  - spectrum.

Card 1/3 The maximum energies and the relative intensities of these components

A Study of the  $\beta^+$ -Decay of  $\text{Ho}^{160}$ .

20-4-15/51

are given. The half life is equal for all components of the spectrum and amounts to  $5,6 \pm 0,7$  hours. From an analysis of the results obtained here two problems arise: 1) To which of the holmium isotopes appertains the positive radiation? 2) By what process are these positrons produced? Are they actually a result of the  $\beta^+$ -decay or are these positrons corresponding to a pair conversion of the corresponding transitions? From the considerations of the authors the following springs: Because of the fact, that the  $\beta^+$  spectrum with a half life of 5,6 hours was observed from a source, which was separated from Er after 45 hours, the assumed  $\text{Ho}^x$  is obtained from  $\text{Er}^x$  just like  $\text{Ho}^{160}$ .

( $\text{H}^x$  denoting an unknown holmium isotope). 2) The fact, that the ratio  $S_{\beta^+}/S_{e^-}$  from both sources is equal, speaks in favour of a convin-

cing similarity not only of the periods of  $\text{Ho}^{160}$  and  $\text{Ho}^x$ , but also of the periods of  $\text{Er}^{160}$  and  $\text{Er}^x$ . The fraction of Erbium, which had been kept for 110 hours after the separation was used in an additional experiment, which furnished the same results. The greater number of electrons is probably coming from the  $\beta^+$ -decay of  $\text{Ho}^{160}$ . The mass difference between  $\text{Ho}^{160}$  and  $\text{Dy}^{160}$  amounts to a value of not less than  $2920 \pm 100$  keV. Further details are given.

TITLE: The Decay of  $Tb^{160}$  and  $H^{160}$  and the Level Scheme of  $Dy^{160}$   
(Raspad  $Tb^{160}$  i  $Ho^{160}$  i skhema urovney  $Dy^{160}$ )

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Fizicheskaya, 1958  
Vol. 22, Nr 2, pp. 101-125 (USSR)

ABSTRACT: Radioactive  $Tb^{160}$  was here obtained by irradiation with slow neutrons of chemically pure (99.99%)  $Tb_2O_3$ . The position and relative intensity of 19 lines was carefully measured in the conversion spectrum. The decomposition of the known line 963 + 966 keV into two components is essentially new. The relative intensities of the  $\gamma$ -transitions were obtained by means of a division of the line areas through the corresponding photoelectric absorption factor. The values were because of the absorption of the  $\gamma$ -rays corrected in the source itself and at the walls of the cylinder, as well as because of the absorption of the photoelectrons in the target and in the slits of the counter. The obtained relative intensities

Card 1/3

The Decay of  $Tb^{160}$  and  $H^{160}$  and the Level Scheme of  $Dy^{160}$  48-22-2 2/17

of the  $\gamma$ -lines in the spectrum of photoelectrons are in the range of  $\pm 20\%$  in agreement with those of references 5 and 6. The measurements of the conversion spectrum show that the soft component is twice as weak as the hard one. The multiplicity of these transitions apparently is equal and between the intensities of the  $\gamma$ -lines the same relation

must exist. - Radioactive  $Ho^{160}$  was obtained by irradiation of a tantalum target with protons with an energy of up to 660 MeV. The erbium and holmium fractions were chromatographically separated from the target. In the conversion spectrum all conversion lines of  $Ho^{160}$  that had been obtained in reference 8 were also confirmed here and many new ones discovered. It is shown that the transitions to the upper levels are permitted ones. The small number of positrons (one positron) per decay is explained by the fact that at the low decay-energy the K-capture is dominating. When the decay to two upper levels is considered permitted  $K/\beta^+$  can be determined according to the tables by Zweifel (ref. 10). The values 5400 and 400 thus obtained are very high, consequently a considerable part of all conversions

Card 2/3

of  $Ho^{160}$  must take place by way of K-capture. In the

The Decay of Tb<sup>160</sup> and H<sup>160</sup> and the Level Scheme of Dy<sup>160</sup> 48-22-2-2/17

second short chapter the determination of the multiplicity of transitions is shown and its results are given in the form of a table. - In the third chapter the scheme of the Dy<sup>160</sup>-levels is treated. A level scheme of Dy<sup>160</sup> was here compiled with the use of all experimental data, theoretical considerations and the analogy with the neighboring nuclei. This scheme in the best manner corresponds to all data. All arguments confirming this scheme are given here and all facts contradicting this scheme or facts which cannot be explained are enumerated. There are 8 figures, 12 tables, and 19 references, 8 of which are Soviet.

TITLE:

Positron Spectra of the Dysprosium Fraction (Spektry pozitronov disproziyevoy fraktsii)

PERIODICAL:

Izvestiya Akademii Nauk SSSR, Seriya Fizicheskaya, 1958  
Vol. 22, Nr 2, pp. 208-210 (USSR)

ABSTRACT:

The mentioned dysprosium fraction was here obtained by separation from the tantalum target, which was irradiated by protons with an energy of 660 MeV. In this connection it is stated, that no data can be found in publications on the dysprosium isotope with a half life of 20 hours. Dy<sup>157</sup> was ascribed to the eighth period (reference 2). From reference 3 it can be seen, that another Dy<sup>155</sup> exists with a half life of 10 hours. In order to determine which isotopes are contained in the here obtained preparation, its conversion spectrum was investigated, which resulted in the determination of 11 peaks of conversion electrons. 6 of these possessed the same half life of  $11 \pm 2$  hours. The energy of the electrons amounted to  $180 \pm 10$ ,  $270 \pm 15$ ,  $320 \pm 20$ ,  $400 \pm 25$ ,  $465 \pm 30$  and  $610 \pm 30$  keV. It was assumed, that these are K-electrons, possessing

Card 1/3

Positron Spectra of the Dysprosium Fraction

48-22-2-14/17

the transition energies 230, 320, 370, 450, 515, and 660 keV. Such transitions "apparently" correspond to  $Dy^{155}$  or  $Dy^{157}$ . The ratio of the number of positrons and of the number of conversion electron transitions with  $h\nu = 515$  keV was established to be 37,5. A half life of 4,7 days and energies of 98, 112, 132 and 162 keV here corresponded to the four groups of conversion electrons. A comparison with the conversion spectrum of the dysprosium fraction as given in reference 3 permits to assume, that in this case it is concerned with the lines K-148, K-162, K-182 and K-210, which occur in the decay of  $Tb^{155}$  (the first three of them), which also pertains to the decay of  $Dy^{155}$  and  $Dy^{157}$ . Concerning the 20 hours decay period which was found in this investigation in the dysprosium fraction, it is stated here, that its origin remained unclear. Concerning this it is remarked, that in the measurements of the terbium fraction on a ketron (reference 4) positrons from a decay with a half life of 18 hours and a limit energy of  $\sim 2800$  keV were observed, which is near to the found half life of  $\sim 20$  hours. For this reason it is assumed, that the respective positron spectrum refers to the isotope Tb with a half life of 18 hours. There are 4 figures and 4 references, 3 of which are Soviet.

TITLE: Study of Positron Spectra of Neutron-deficient Isotopes

PERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, 1960,  
Vol. 24, No. 3, pp. 283-287

TEXT: The article under review was read at the Tenth All-Union Conference on Nuclear Spectroscopy (Moscow, January 19 - 27, 1960). The authors studied the positron spectra of some neutron-deficient isotopes obtained by bombarding a tantalum target with 680-Mev protons. The authors used a  $\beta$ -spectrometer with triple beam focusing. Results are given according to elements. Lutetium: The hardest component recorded had an energy limit of about 2,800 kev. All spectral regions with an energy exceeding 1,500 kev corresponded to one and the same half-life of  $85 \pm 18$  min (Fig. 1). Thus, it may be seen from the Curie curve shown in Fig. 2 that the energy limit of the  $\beta^+$ -spectrum was  $2,800 \pm 200$  kev, corresponding to a half-life of  $56 \pm 12$  min. The above component can, therefore, be ascribed to  $\text{Lu}^{167}$

Card 1/3

Study of Positron Spectra of Neutron-  
deficient Isotopes

S/048/60/024/03/05/019  
B006/B014

(55 min). The Curie curve of this isotope is shown in Fig. 3. The problem of the  $\beta^+$ -spectrum with the energy limit of 2,800 kev and  $T = 85$  min has not yet been solved. Such an isotope is unknown. Two explanations are possible: 1) Such an Lu isotope as, e.g.,  $\text{Lu}^{168}$  actually exists. In this case also a  $\gamma$ -radiation would have to exist for this half-life, which has not yet been observed. 2) It is the radiation of the 75-minute Yb isotope ( $\beta^+$ -energy limit 2.95 Mev); the presence of such an impurity is not impossible. Thulium: The authors recorded a  $\beta^+$ -spectrum with an energy limit of 2.1 Mev (7.3 hours -  $\text{Tm}^{166}$ ) and one with 137 min ( $\text{Tm}^{163}$ ). As shown in Fig. 4, the spectrum consists of two components with the energy limits  $1,050 \pm 80$  and  $400 \pm 50$  kev with an intensity ratio of 1 : 0.7. The  $\text{Tm}^{163} - \text{Er}^{163}$  mass difference was  $\approx 2,070$  kev. Other authors found 2.1 and 2.24 Mev. Erbium: Intense positron emission with an energy limit of 1,300 kev ( $\sim 2.5$  hours) was found, further one with  $115 \pm 15$  min. This spectrum also consisted of two components with the energy limits  $1,900 \pm 100$  and  $2,980 \pm 100$  kev, and an intensity ratio of 5 : 1. Also the electron-conversion line with 900 kev (2 hours), which was observed for the first time by I. A. Dneprovskiy, was detected. Dysprosium: The

Card 2/3

Study of Positron Spectra of Neutron-deficient Isotopes

B006/B014

dysprosium spectrum also consisted of two components with the energy limits  $2,700 \pm 100$  and  $1,650 \pm 100$  kev, and an intensity ratio of 3 : 1. Two possibilities concerning the origin of these components are discussed. There are some facts which contradict the existence of a decay series

$Dy^{154}$  3hs,  $Tb^{154}$  18hs,  $Gd^{154}$ , but speak in favor of  $Dy^{152}$  3hs,

$Tb^{152}$  18hs,  $Gd^{152}$ . Besides, the authors also detected a  $\beta^+$ -spectrum with an energy limit of about 900 kev (10 hs - presumably  $Dy^{155}$ ). A. S. Basina is mentioned. Finally, the authors thank I. A. Yutlandov and V. M. Khalkin for carrying out the chemical work, as well as K. Ya. Gromov and L. K. Peker for their discussions. There are 5 figures and 17 references, 8 of which are Soviet.

TITLE: A beta-gamma coincidence scintillation spectrometer with a low gamma-gamma coincidence background/Transactions of the Fifteenth Annual Conference on Nuclear Spectroscopy and Nuclear Structure held at Minsk 23 January to 2 February 1965/  
SOURCE: AN SSSR. Investiya. Seriya fizicheskaya, v. 29, no. 12, 1965, 2141-2146  
TOPIC TAGS: beta decay, beta spectroscopy, gamma spectroscopy, gamma background, scintillation spectrometer.  
ABSTRACT: A beta-gamma coincidence scintillation spectrometer is described in which special means are employed to reduce the gamma-gamma coincidence background. Such means are particularly desirable when investigating complex decay schemes where there are many gamma cascades. In this spectrometer the gamma rays are detected with an NaI crystal and the beta particles with an anthracene crystal or a plastic scintillator. Between the source and the beta detector is mounted a thin (~0.3 mm) film of plastic scintillating material in a highly reflecting housing of ~1 μ aluminum foil. The photomultipliers associated with the beta detector and the film scintillator are connected to a coincidence circuit, and only coincidences are recorded as beta particles. Gamma rays that enter the beta detector cannot produce a flash in the thin film scintillator and thus are not recorded. The energy lost by a beta particle traversing  
Card 1/2

L 13874-66

ACC NR: AP6002877

the film scintillator and its housing was found to be 80-100 keV; this energy loss makes the instrument unsuitable for investigation of soft beta spectra. The behavior of the instrument is discussed in some detail, and it is concluded that in cases favorable to its use the gamma-gamma coincidence background can be reduced by a factor of 10 to 20 without serious reduction in the true beta-gamma coincidence counting rate. The instrument was employed to record the spectrum of gamma rays in coincidence with positrons of the 1500 keV end-point component of the beta spectrum of  $\text{Eu}^{146}$ . The source was the gadolinium fraction separated chromatographically from a tantalum target bombarded with 600 MeV protons and aged for two or three months. After aging the material consisted almost entirely of  $\text{Gd}^{146}$  and the  $\text{Eu}^{146}$  in equilibrium with it. In the gamma ray spectrum there were found two approximately equal peaks corresponding to gamma-ray energies of 635 and 745 keV. It is concluded that the 1500 keV end-point beta decay goes to the 1380 keV level in  $\text{Sm}^{146}$ . In these measurements the gamma-gamma coincidence background did not exceed 10% of the true beta-gamma coincidence counting rate. When the film scintillator was removed the gamma-gamma coincidence counting rate was approximately equal to the true beta-gamma coincidence rate. It is concluded that the use of the film scintillator in coincidence with the beta detector reduced the gamma-gamma coincidence background by a factor between 10 and 20. ABSTRACT: The article is a description of an experiment in which a  $\beta\gamma$ -spectrometer was used to measure the coincidences of positrons of the hard component of the  $\beta^+$ -spectrum of  $Tu^{166}$  with  $\gamma$ -radiation. The source of  $Tu^{166}$  was  $Yb^{166}$  contained in an ytterbium fraction. The latter was emitted from a tantalum target irradiated with 660 Mev protons. An analysis of the results is carried out to determine the decay and coincidences at various quantum levels. The authors thank Ye. P. Grigor'yev and V. M. Mikhaylov for valuable discussions, and also Zh. Zhelev, A. V. Kudryavtseva, and G. A. Mironov for assistance in receipt of the sources. Orig. art. has: 3 figures and 3 formulas. [JPRS]

ABSTRACT: To overcome some of the difficulties involved in using ordinary spectrometers for the study of gamma-ray coincidence with low intensity hard components of beta spectra, a special magnetic  $\beta\gamma$ -spectrometer was designed and built at the Leningrad University. The schematic diagram of the instrument is shown in the enclosure. An 8-bladed fan-shaped diaphragm is used to separate the electron and positron beams. The electronic circuit, the operation of the instrument, and its capabilities are described, as are a number of experiments conducted. Results are plotted in curves and analyzed. The authors thank Yu. G. Zhukovskiy for participating in the early design of the instrument and to V. Z. Kaufman, student at the Leningrad State University, for assisting in its construction.

TITLE: Spin of sub 71 lu sup 170 sub 99 [This paper was presented at the 16th Annual Conference on Nuclear Spectroscopy and Nuclear Structure held in Moscow 26 Jan-3 Feb 1966]

SCURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 3, 1966, 554-559

TOPIC TAGS: nuclear physics conference, nuclear spin, lutetium, beta decay, proton bombardment

ABSTRACT: The beta<sup>+</sup> gamma coincidence method is used to determine the spin of Lu<sup>170</sup> which has a beta<sup>+</sup> decay to the lower rotational band of Yb<sup>170</sup>. The Lu<sup>170</sup> sample was obtained from Hf<sup>170</sup>, with the usual bombardment of a tantalum target with 660 mev protons. The coincidences of ~1660 kev positrons and gamma radiation was studied in the range of 10 to ~250 kev. Coincidences were not observed at energies of 193 and 84 kev, nor were beta<sup>+</sup> transitions from the Lu<sup>170</sup> ground state to the 2<sup>+</sup> and 4<sup>+</sup> levels of Yb<sup>170</sup>. It is shown that the ground state spin of Lu<sup>170</sup> is zero - a conclusion that is supported by theoretical arguments. Finally, the

purity of the isotopic spin in the ground state of Lu<sup>170</sup> is determined. The coefficient of impurity isospin ( $5 \times 10^{-3}$ ) determined theoretically is 20 times greater than the experimental value, which fact needs theoretical explanation. The authors thank L. A. Sliv. and Yu. I. Kharitonov for valuable discussions.

TITLE: Beta + gamma coincidences during the decay of Tb sup 152 yields Gd sup 152 21

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 8, 1966, 1286-1291 19

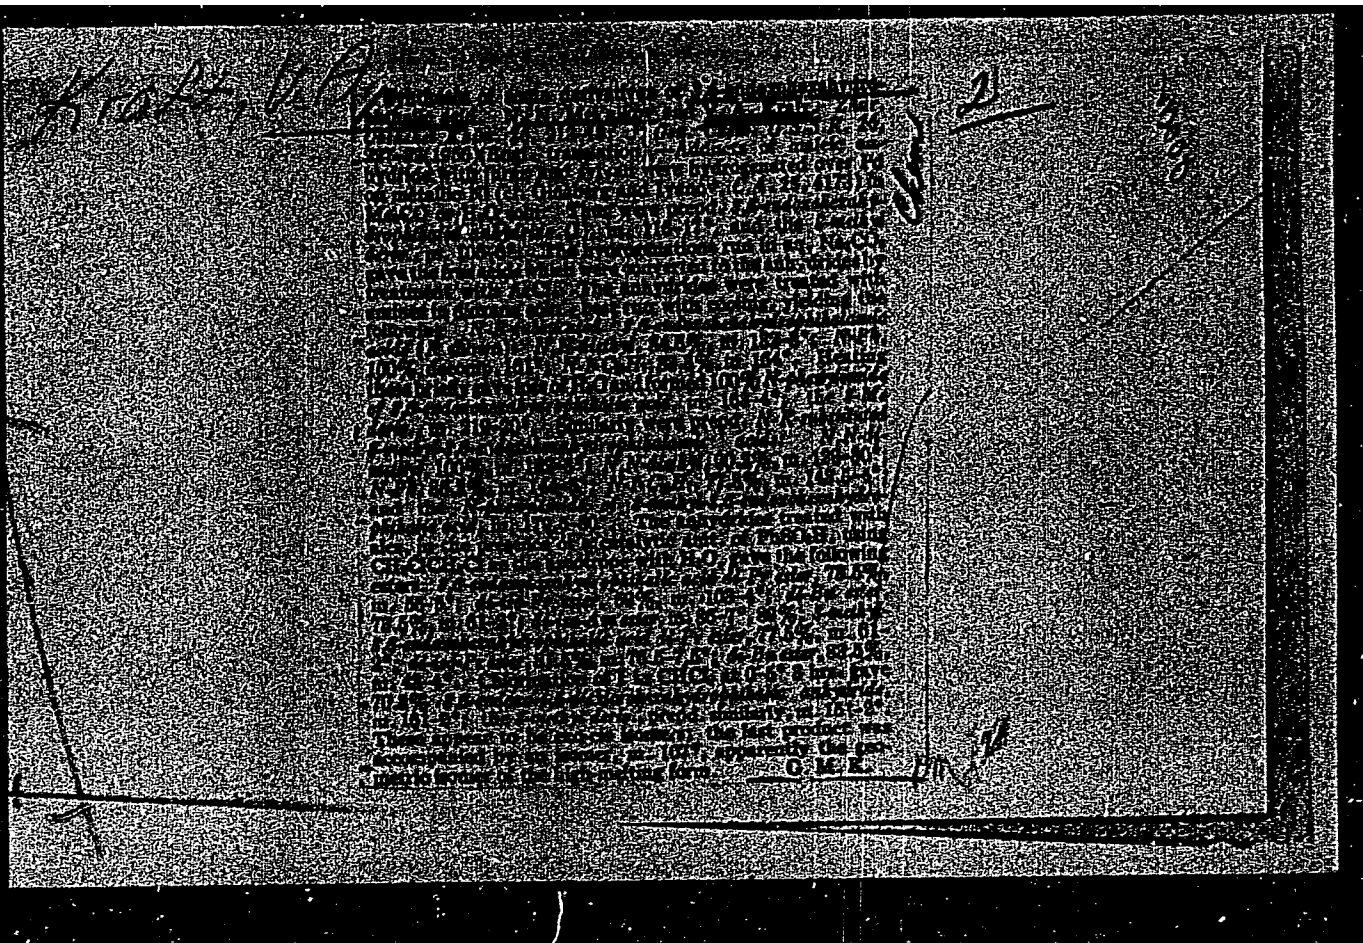

TOPIC TAGS: gamma spectrometer, gamma radiation, position

ABSTRACT: These coincidences were measured with the object of procuring more information on the spin of the  $Tb^{152}$  nucleus, which has not previously been experimentally determined. A magnetic  $\beta\gamma$ -coincidence spectrometer was used: the magnetic spectrometer isolated positrons within a specified energy range and the  $\gamma$ -spectrometer recorded the  $\gamma$ -radiation coinciding with these positrons. The measurements pertained to the spectrum of  $\gamma$ -rays coinciding with positrons of the following energies:  $\sim 2500, \sim 2000, \sim 1500$ , and  $\sim 1200$  kev. Findings: With decrease in positron energies, coincidences with  $\gamma^{272}$  quanta are observed. The fundamental state of  $Tb^{152}$  cannot have the characteristic  $1^{+}3^{+}$ . The most probable values of the spin and parity of the fundamental state of  $Tb^{152}$  must be regarded as  $1^{-}$ . "In conclusion, the authors wish to express their deep appreciation to L. V. Moskvina and Yu. V. Norseyev for isolating terbium from dysprosium, and they thank Zh. T. Zhelev and K. Ya. Gromov for cooperation in procuring the sources." Orig. art.

On Some Derivatives of 4,5-Dichloro-3,6-endoxohexahydro Phthalic Acid (O nekotorykh proizvodnykh 4,5-dikhlor-3,6-endoksogeksa-gidroftalevoy kisloty)

PERIODICAL:

Zhurnal obshchey khimii, 1959, Vol 29, Nr 3, pp 968-971 (USSR)

ABSTRACT:

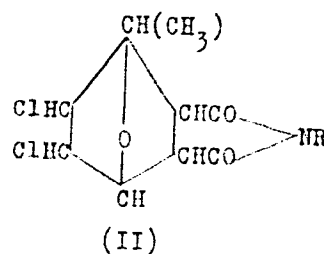

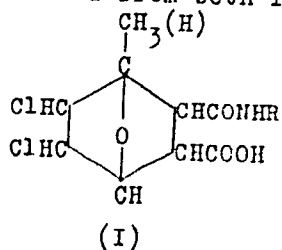

The synthesis of the anhydrides of 4,5-dichloro-3,6-endoxohexahydro phthalic- and 3-methyl-4,5-dichloro-3,6-endoxohexahydro phthalic acid, which the authors carried out by chlorination of the anhydride of 3,6-endoxo- and 3-methyl-3,6-endoxo-1,2,3,6-tetrahydro phthalic acid, had to be investigated by them more thoroughly, all the more as there is no mention in publications concerning the properties of 4,5-dichloro-3,6-endoxohexahydro phthalic acids and their derivatives, except the corresponding dibromo derivatives (Refs 2-9,10). In the work under review the authors investigated the synthesis of various derivatives of 4,5-dichloro-3,6-endoxohexahydro phthalic acid more closely. By the esterification of 3-methyl-4,5-dichloro-3,6-endoxohexahydro phthalic acid and of 4,5-dichloro-3,6-endoxohexahydro phthalic acid with various alcohols in the presence of benzene sulfo acid, the esters,

 TOPIC TAGS: phthalic acid, phthalic anhydride, ethanol  
 ABSTRACT: Acid esters of 3,6-endoxohexahydrophthalic acid and 4,5-dichloro-3,6-endoxohexahydrophthalic acid and complete esters of 3,6-endoxohexahydrophthalic acid were prepared. The acid esters were obtained by heating on a water bath a mixture of equimolar amounts of the acid anhydride and an aryloxy ethanol: 2,4-dichlorophenoxyethanol was reacted with 3,6-endoxohexahydrophthalic anhydride; 2,4-dichlorophenoxyethanol and 2,4,5-trichlorophenoxyethanol were reacted with 4,5-dichloro-3,6-endoxohexahydrophthalic anhydride. All the compounds thus synthesized had not been previously reported in the literature. Their formulas, yields, melting points, and molecular weights are tabulated. Orig. art. has: 1 table.

TITLE: Effect of defoliants on some products of photosynthetic assimilation of carbon dioxide

SOURCE: Fiziologiya rasteniy, v. 13, no. 4, 1966, 595-601

TOPIC TAGS: defoliant, defoliant effect, photosynthesis, plant physiology, ~~defoliant~~, ~~defoliant~~ defoliant agent, plant morphology, plant sensibility

ABSTRACT: The radioactive tracer method was used in studying the fixation of  $CO_2$  in plant tissue treated with defoliants. Fig. 1 shows the effects of defoliants on the intensity of  $C^{14}O_2$  fixation by cotton and bean leaves. Treatment with Butiphos and BEXT caused decreased photosynthetic fixation of labeled  $CO_2$  in bean and cotton plants. The amino acid fraction increased in cotton plants, while labeled alanine and aspartic acid increased in both species. Both defoliants increase the amount of organic and phosphoric acids.  $CO_2$  fixed in polysaccharides is decreased while pretreatment of the plants by

TITLE: Optimal shapes of radar pulses 210-2/INT(1)/INT(1)/INT(1)/INT(1)

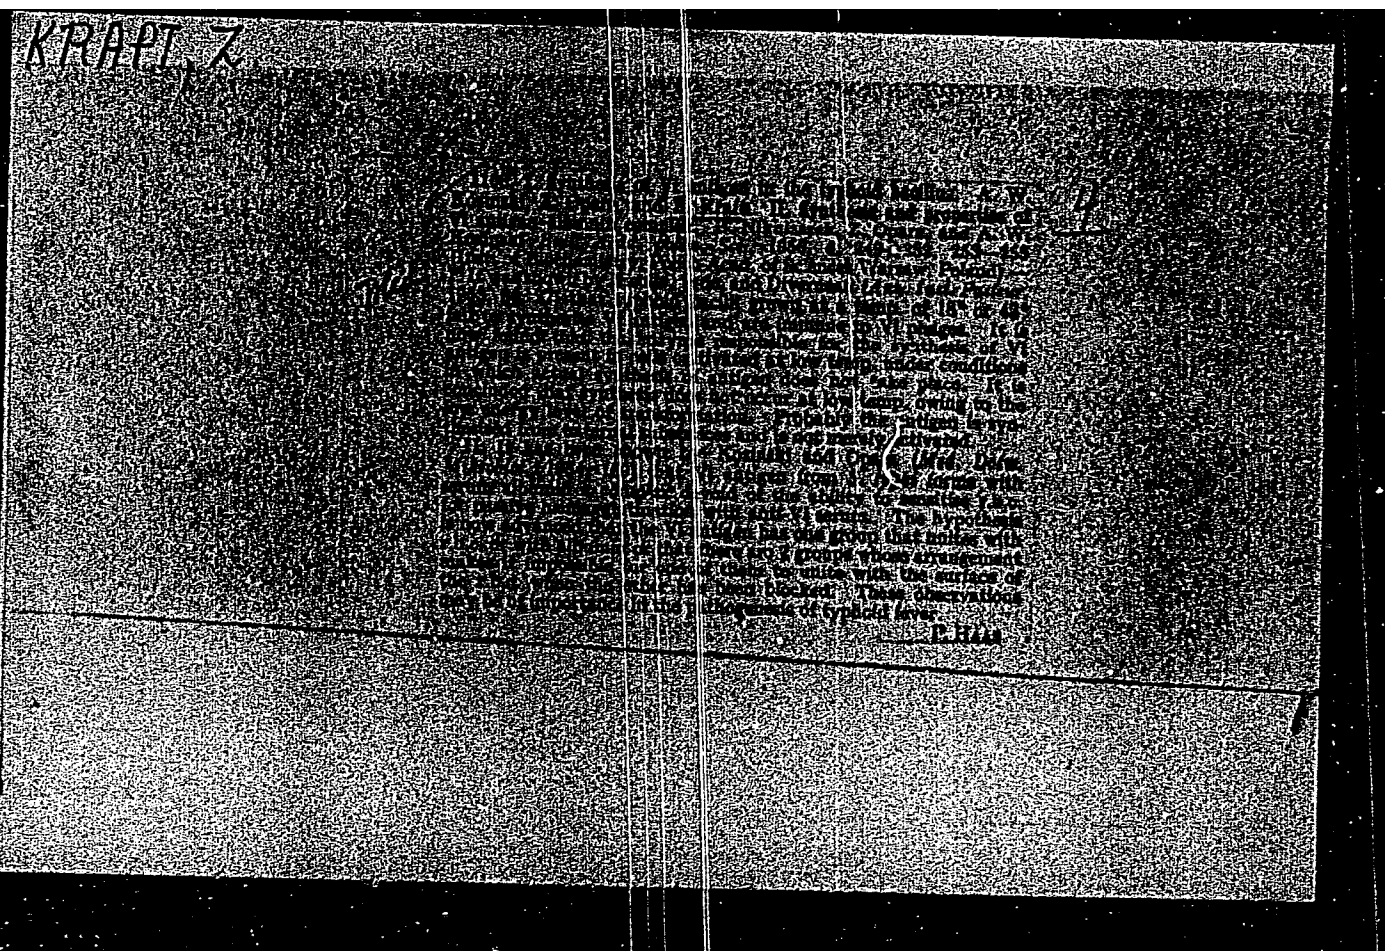

SOURCE: Radiotekhnika, v. 20, no. 2, 1965, 26-32

TOPIC TAGS: radar pulse; radar pulse shape

ABSTRACT: Radar-pulse shapes are found which ensure minimum error in finding target coordinates when the radar receiver is optimal. A receiver that finds the target coordinates by the method of maximum likelihood is regarded as asymptotically optimal; a pulse shape that ensures min is regarded as optimal. The pulse shape ensuring maximum accuracy in determining range is described by:

$$I_r = - \int \int \left( \frac{\partial^2}{\partial t_1 \partial t_2} \right) s(t_1) s(t_2) dt_1 dt_2$$

TITLE: Viscosimeter with Induction Indicators (Viskozimetr s induktivnymi datchikami)

PERIODICAL: "Izmeritel'naya Tekhnika", No 5, Sep-Oct 1957, pp 78-79 (USSR)

ABSTRACT: The article presents a suggestion for viscosimeter design with a falling solid ball, used for viscosity measurements in non-transparent fluids or in fluids under high pressure, in a wide temperature range, where the presently practiced Stoke's method (with falling ball in transparent fluids) is impracticable. The proposed viscosimeter comprises two series-connected inductive indicators and two condensers, which form the oscillating circuit of a tube generator. When the metal ball passes the inductive indicators, electric impulses are generated in a load resistance which is inserted in the anode circuit of the oscillator. The anode current is measured by a milliamperemeter. For the case of high speed of the ball, it is suggested to utilize an electronic oscillograph (as is done in the case illustrated by a circuit diagram in the article). It is stated that in this case the described viscosimeter is used, in connection with the oscillograph "30-7", the impulse amplitude would be not less than 10 volt.

Card 1/2

Viscosimeter with Induction Indicators

115-5-33/44

The suggested viscosimeter design is claimed to have considerable advantages as compared with viscosimeters utilizing the induction method or the pulsation method. The inductive indicators under consideration are recommended for work with conventional viscosimeters.

The article contains 1 circuit diagram and 3 references.

TITLE: The Investigation of the Operation of Laboratory Mixers by Means of Magnetic Indicators (Izucheniye raboty laboratornykh smesiteley pri pomoshchi magnitnykh indikatorov)

PERIODICAL: Zavodskaya Laboratoriya, 1958, Vol. 24, Nr 7, pp. 893 - 895 (USSR)

ABSTRACT: The apparatus constructed is based on the measurement of the magnetic conductivity of the samples in the low-frequency magnetic field. The instrument measuring the magnetic susceptibility was constructed by Ya.A.Kraftmakher. The measuring unit is an H-shaped armature on which three induction coils are arranged. The sample to be investigated is attached in such a way to the measuring unit that the magnetic flux passes through it; thus the inductive voltage in one of the coils is changed and the voltage of the measuring unit serves as a standard for the magnetic susceptibility of the sample. From the schematic representation of the apparatus given may be seen that a low-frequency generator, the measuring unit, a low-frequency amplifier, a detector, a lamp voltmeter as well as a visual in-

Card 1/2

The Investigation of the Operation of Laboratory  
Mixers by Means of Magnetic Indicators

SOV/32-24-7-5 1/65

indicator and a supply pack are assembled. The instrument has six measuring ranges of from  $10^{-4}$  to  $10^{-1}$  units of magnetic susceptibility in the CGSM system: the degree of mixing is determined by the measuring of the concentration of the magnetic powder in the samples taken from different places. The concentration of the magnetic powder is measured according to the magnetic susceptibility of the specimens pressed from the samples to be investigated. Granular sizes of quartzite of up to 0,5mm were used in the experiments; iron powder of 2,5%  $\text{Ca(OH)}_2$ , 0,5% sulfite alcohol vinasse, 8% water and 1,5% iron powder served as indicator. The results obtained were obtained from the mean value of the magnetic susceptibility and an equation; a diagram is given. There are 3 figures.

TITLE: On the determination of the electrodynamic constant

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy,  
Fizika, no.1, 1962, 175-176

TEXT: It is pointed out that in a teaching laboratory the electrodynamic constant is usually determined by periodically charging and discharging a capacitor through a tangent galvanometer. [Abstractor's note: The electrodynamic constant referred to here is the ratio of the electromagnetic to the electrostatic units of charge.] When the sensitivity of the galvanometer is small, a large current must be passed through it (several hundred milliamps) and the charge-discharge key does not operate satisfactorily. In order to obviate this difficulty the author puts forward the method illustrated by Fig.1. This circuit includes an additional micrometer and a key K<sub>2</sub>. When the key is in the left-hand position the micrometer measures the discharge current which is proportional to C and the voltage

Card 1/ 5

E032/E114

across the condenser. When the key is in the right-hand side position the micrometer records a known fraction of the current passing through the tangent galvanometer. The resistor  $R$  is chosen so that the current passing through the micrometer is the same for both positions of the key  $K_2$ . The resistors  $R_1$  and  $R_2$  are chosen so as to produce a suitable deflection in the tangent galvanometer. The electrodynamic constant is then equal to

$$\frac{2\pi n C U N}{r H_0 \tan \phi} \frac{R_1 + R_2 + R_0}{R_1}$$

where:  $C$  is the capacitance;  $U$  is the voltage of the battery charging the capacitor;  $N$  is the frequency of  $K_1$ ;  $H_0$  is the horizontal component of the earth's magnetic field;  $n$  is the number of turns on the tangent galvanometer;  $R$  is the resistance of the coil of the tangent galvanometer;  $\phi$  is the deflection of the galvanometer with  $K_2$  in the right-hand position; and  $R_0$  is the internal resistance of the micrometer.

TITLE: Formation energy and concentration of vacancies in tungsten

PERIODICAL: Fizika tverdogo tela, v. 4, no. 8, 1962, 2271 - 2274

TEXT: The formation energy and concentration of vacancies in tungsten was determined from the specific heat whose temperature dependence was measured from 2000 to 3600°K. Temperature of the specimens was modulated on a frequency of some 120 cps by a current (constant + variable components) passing through the specimens. The rise in specific heat at high temperatures was measured as  $\Delta C_p = (U^2/RT^2)A \exp(-U/RT)$ , where U is the formation energy of the vacancies,  $A \exp(-U/RT)$  is the vacancy concentration at temperature T. Measurements and evaluation of this formula yielded for tungsten a vacancy formation energy of 72.5 kcal/g-atom. The vacancy concentration is  $c = 670 \exp(-72500/RT)$ , which at 3600°K is 2.7%. There are 2 figures. ✓

To determine the energy of vacancy formation and the vacancy concentration in Nb, the Institute of Thermophysics, Siberian Department of the Academy of Sciences USSR, has measured the specific heat of Nb in the 1300-2700°K range. Vacuum-degassed Nb specimens, 0.11 and 0.13 mm in diameter and 40-70 mm long, were "trained" at 2000°K at a residual pressure of  $2 \times 10^{-6}$  mm Hg. Results of the measurements show the energy of vacancy formation in Nb to be 47 kcal/g-atom. The vacancy concentration in Nb at the melting temperature reaches 1.2%, while the additional specific heat associated with vacancy formation at the melting temperature is 0.57 kcal/g-atom.

AUTHOR: Kraftmakher, Ya. A. (Novosibirsk)

TITLE: Heat capacity of tantalum in the 1200-2900°K temperature interval

PERIODICAL: Zhurnal prikladnoy mekhaniki i tekhnicheskoy fiziki, no. 2, 1963, 158-160

TEXT: Using the modulation method (Ref. 1: Ya. A. Kraftmakher, PMTF, 1962, No. 5) the author determined the heat capacity of Ta in the 1200-2900°K temperature interval. Between 1200 and 2000°K the heat capacity follows the equation

$$C_p = 5.82 + 0.00068 T \text{ cal/g-at. degree} \quad (1)$$

at higher temperatures there is an additional increase in heat capacity due to the creation of vacancies, and it agrees with the equation

$$\Delta C_p = \frac{u^2}{RT^2} \exp \frac{-u}{RT} \quad (2)$$
